IR ABSORBANCE MEASUREMENT OF VARIABLE COMPOSITION AQUEOUS VOCs

1. INTRODUCTION

This report documents the vapor phase infrared (IR) spectra of five volatile organic compounds (VOCs). These VOCs are acetone, 2-butanone, ethanol, isopropanol, and methanol. Previous studies have relied on the spectral data included in the appendixes of this report to generate Beer's law plots for the determination of absorptivities of the targeted VOCs. Vapor concentrations for the IR absorbance measurements are obtained from the partial vapor pressures generated over the variable composition aqueous VOC solutions. The VOC partial vapor pressure depends upon both solution composition and temperature. The correlation between partial VOC vapor pressure and solution composition at a fixed temperature has been established in a previous investigation.³

The IR absorbance spectra obtained in this report compare quite favorably to those obtained by different instrumental methods.⁴ A traditional laboratory bench Fourier transform infrared (FT-IR) spectrometer was employed in acquiring the raw interferogram data.

2. EXPERIMENTAL METHODS

A detailed description of the equilibrium-vapor cell method for generating quantitative partial vapor pressures has been previously documented in the literature. However, the actual solute/solvent weights were not provided. These weights along with the approximate and the calculated liquid mole percentages are furnished in Table 1 for each solute. The total solution weights were around 190 g and within the capability of the top loading balance (Model AE200; Mettler Instruments Corporation, Hightstown, NJ), which possessed a precision of 0.1 mg.

Acquisition of interferogram data employed the Spectra Calc applications software package (Galactic Industries Corporation, Salem, NH). The filename format of the interferogram data that were collected is tabulated in Table 2. This software package also permitted conversion of interferograms into single-beam spectra and subsequent calculation of absorbance. The computed single-beam spectra were calculated using box apodization. The filenames of the absorbance files have been listed in Table 3. The spectral point spacing for all target analytes was nominally 2/cm. Because the methanol PQR band centered at 1033/cm has rotational fine structure, the spectral point spacings of nominally 0.5/cm, 1.0/cm, and 4.0/cm were also used to allow assessment of band intensity as a function of spectral resolution.

3. ABSORBANCE SPECTRA EVALUATION

Calculation of the IR absorbance spectra requires taking the ratio of the single-beam blank/sample spectra for each target analyte condition to determine the transmittance spectrum. The transmittance spectra are converted to IR absorbance spectra by taking the base ten logarithm of the reciprocal of the transmittance. Three absorbance spectra are obtained for each of the five target analytes whose filenames are listed in Table 3. These three absorbance spectra for each condition are added together and divided by the number of spectra to produce an average. Using these absorbance averages, the associated average deviations are determined for each analyte condition and the filenames are furnished in Table 4. The average deviation, ad, for the spectral region from 750/cm to 1400/cm is computed at each wavenumber with equation 1.

$$ad = \sum |Y - Y_i|/3 \tag{1}$$

The Y is the average spectrum value at a specified wavenumber. The Y_i is one of the absorbance spectrum samples labeled A, B, or C at the specified wavenumber. Three is the number of absorbance spectra used in determining the average.

^{*}Spectral point spacing only for methanol data.

The computation of the average and associated average deviation for each equilibrium-vapor cell condition is accomplished with one of three Spectra Calc programs listed in Appendix A. The program ABCAVG.AB handles most of the absorbance spectra with 2/cm spectral point spacing (see Table 3 for solutes: acetone, 2-butanone, ethanol, and isopropanol). The program ABCFAVG.AB does expect a designation number at the end of the filename indicating the spectral point spacing. This program works on all methanol data with the exception of the 0.5/cm

spectral point spacing indicated by the number five at the end of the filename. The methanol absorbance spectra with 0.5/cm spectral point spacing are processed with the third program ABCSAVG.AB. This particular program avoids problems with the large file size by requiring only three memory slots to be open at a time for the computations. Table 5 illustrates the computed average, average deviation, and percent deviation absorbance results for the Q band of methanol for 0.5/cm point spectral spacing using a 2 mol % aqueous solution. The average and average deviation files from the 750/cm to 1400/cm spectral region (see Table 4) are reported in Appendixes B through F. The percent deviations are not provided in the appendixes, because they are easily computed from the average and average deviation absorbance data provided.

The percent deviations provide a convenient means of assessing the absorbance band cutoff limits. To evaluate the integrated peak area, it is necessary to establish band cutoff limits. An absorbance band cutoff limit is defined in this particular case as the wavenumber location at which the average signal strength equals three times the average deviation of that signal. This translates into a percent deviation of about 33%. Figures 1 and 2 furnish an examples of determining the band cutoff limits for acetone solutions of 1.05 and 6.19 mol % in the liquid phase. The lower band cutoff (see Figure 1) occurs at approximately 1157.6/cm and 1163.4/cm for the 1.05 and 6.19 mol % solutions, respectively. The upper band cutoff (see Figure 2) falls at about 1259.9/cm and 1271.5/cm for the 1.05 and 6.19 mol % solutions, respectively. As expected, the band cutoff limits for the higher concentration solution are slightly wider than those of the more dilute solution.

A listing of the solute mole percent in the liquid phase, solute vapor pressure over the solution, and concentration in the vapor phase, that are associated with each of the average and average deviation absorbance spectra in Appendixes B through F, are provided in Table 6. The concentration in the vapor phase is determined by using the ideal gas law with the details illustrated by equation 2.

$$n/V = P/RT = (P Torr)/[(0.08205 l-atm/K-mole)(760 Torr/atm)(1000 l/m3)(T K) (2)$$

Where n is the number of moles; V is the volume in m³; P is pressure in Torr; and T is temperature in degrees Kelvin. For a vapor temperature of 22 °C, conversion from vapor pressure in Torr to moles/m³ with equation 2 reduces to multiplying the vapor pressure by a factor of 0.05433.

Table 5. Comparison Between Computed and Calculated 2 mol % Methanol in Water Peak Absorbances

4. SUMMARY

In summary, the absorbance spectral data previously acquired by the equilibrium vapor cell method, in the form of average and average deviation absorbance files, are compiled in a set of appendixes. Use of the average and average deviation files as a relative percent deviation furnishes a means of determining band cutoff limits for various target vapor concentrations. Actual solute and solvent weights to gravimetrically generate vapor concentrations are documented in this report. The filenaming conventions for interferogram, as well as absorbance spectral data produced with box car apodization, is supplied in tabular form. Vapor pressures in units of Torr and vapor concentration in units of moles/m³ associated with absorbance spectra are listed to ensure completeness of this report.
